Drugs of abuse elevate dopamine levels in the nucleus accumbens (NAc) and alter transcriptional programs believed to promote long-lasting synaptic and behavioral adaptations. In this presentation, I will discuss our recent efforts leveraging singlenucleus RNA-sequencing (snRNA-seq) and Assay for Transposase Accessible Chromatin (snATAC-seq) to generate a comprehensive molecular atlas of cell subtypes in the NAc, defining both sex-specific and cell type-specific responses to acute and repeated drug experience in a rat model system. Our work demonstrates that psychostimulant drugs such as cocaine recruit activitydependent transcriptional programs in the NAc to subsequently initiate chromatin reorganization at enhancer elements near genes implicated in synaptic function. Moreover, we show that direct activation of a core dopamine-driven gene program with a multiplexed CRISPR strategy initiates a secondary synapse-centric transcriptional profile, alters striatal physiology in vitro, and enhances cocaine sensitization in vivo. Taken together, these results define the genome-wide transcriptional response to cocaine with cellular precision, and highlight the mechanisms by which drugs of abuse initiate experience-dependent chromatin remodeling.
